

HOW DO YOU IRRIGATE DURING HEATWAVES?

Researchers at the University of California Davis are conducting a multi-year, multi-phase study to develop and improve cultivar-specific irrigation recommendations for maintaining winegrape quality and quantity in the face of longer, hotter, and more frequent heat waves.

By participating in this study, you will enable us to refine our study designs in the vineyards and field, and aid in providing solutions tailored to the needs of growers and industry. We will use the information you provide as guidance in the dissemination of results back to you as well.

This initial survey will help researchers to broadly evaluate how vineyard managers are currently responding to heat waves.

We welcome responses from growers, vineyard managers, farm advisors, technical service providers, and other viticulture professionals.

Please follow the link below to complete the survey. Responses are requested by June 1st
